

Reference
Oscillator

```
graph LR; RO[Reference Oscillator] --> PD[Phase detector]; PD --> LPF[LPF]; LPF --> VCO[VCO]; VCO --> Out[ ]; VCO --> Div[1/N]; Div --> PD;
```

This diagram illustrates a Phase-Locked Loop (PLL) system. It consists of four main functional blocks connected in a feedback loop. The process begins with a Reference Oscillator, which provides a stable reference signal to the Phase detector. The Phase detector compares this reference signal with the feedback signal and generates an error signal. This error signal is then filtered by a Low-Pass Filter (LPF) to remove high-frequency components. The filtered signal is fed into the Voltage-Controlled Oscillator (VCO), which adjusts its frequency based on the error signal. The output of the VCO is the final locked signal, which is also fed back through a frequency divider (labeled 1/N) to the Phase detector, completing the loop.
