 $\Lambda = 450 \,\mathrm{MeV}$ potentials.

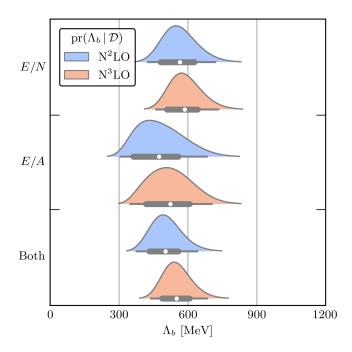

FIG. 1. The analog of Fig. 4 in the main text, but for the $\Lambda = 450 \text{ MeV}$ potentials. The posteriors for the EFT breakdown scale Λ_b using orders through N²LO (blue bands) and N³LO (red bands) corresponding to Fig. 15 in the main text. The upper pair of posteriors comes from analyzing E/N, the middle pair from E/A, and the bottom from a combined analysis. In all cases a Gaussian prior centered at $\Lambda_b = 600 \pm$ 150 MeV is used. The combined N³LO posterior is consistent with the $\Lambda_b \approx 600 \text{ MeV}$ found when considering free-space NN scattering observables [1].

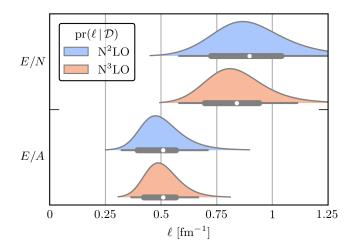

FIG. 2. The analog of Fig. 5 in the main text, but for the $\Lambda = 450 \,\text{MeV}$ potentials. Length-scale posteriors organized similarly to Fig. 1. A scale-invariant prior proportional to $1/\ell$ is used, and each length scale is relative to the $k_{\rm F}$ of each system. If we were to use a single $k_{\rm F}$ prescription, the length scales in PNM and SNM, $\ell_{\rm PNM}$ and $\ell_{\rm SNM}$, respectively, would transform just as $k_{\rm F}$, making the posteriors shift towards agreement.

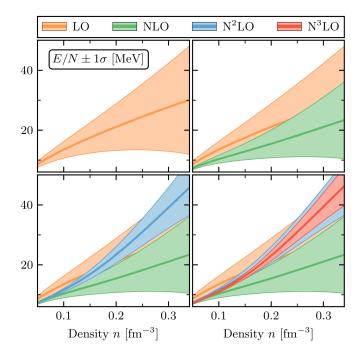

FIG. 3. The analog of Fig. 5 in the main text, but for the $\Lambda = 450 \text{ MeV}$ potentials. The energy per particle in PNM with truncation uncertainties, using a $\Lambda = 450 \text{ MeV}$ potential of Ref. [2]. Bands indicate 68% credible intervals.

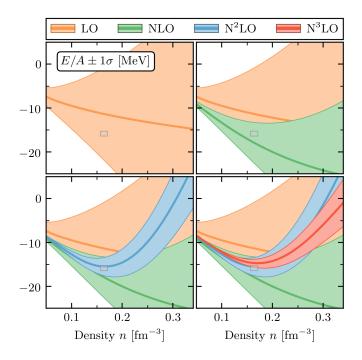

FIG. 4. The analog of Fig. 7 in the main text, but for the $\Lambda = 450 \text{ MeV}$ potentials and similar to Fig. 3 but for SNM. The gray box depicts the empirical saturation point, $n_0 = 0.164 \pm 0.007 \text{ fm}^{-3}$ with $E/A(n_0) = -15.86 \pm 0.57 \text{ MeV}$, obtained from a set of energy-density functionals [2, 3].

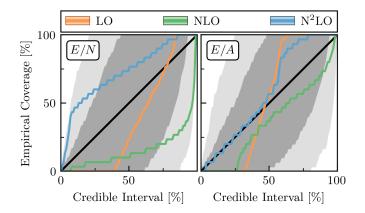

FIG. 5. The analog of Fig. 8 in the main text, but for the $\Lambda = 450$ MeV potentials. Credible-interval diagnostics for the E/N(n) (left-hand side) and E/A(n) uncertainty bands (right-hand side); for details see Ref. [4]. At each order we construct an uncertainty band for the upcoming correction (not the full truncation error) and test whether the next order is contained within it at a specific credible interval. The expected size of fluctuations due to the finite effective sample size of the curves is depicted using dark (light) gray bands for the 68% (95%) interval. Both bands are quite large, which shows that correlations are crucial to assess whether truncation errors have been properly assigned.

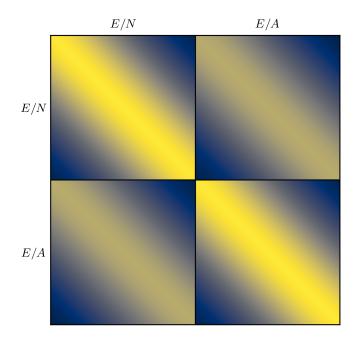

FIG. 6. The analog of Fig. 11 in the main text, but for the $\Lambda = 450$ MeV potentials. Total correlation matrix of E/N(n) and E/A(n) assuming a multitask GP model that was trained to order-by-order results. Each submatrix uses the same grid spaced linearly in $k_{\rm F}$. The diagonal blocks show the autocorrelation, and the off-diagonal block is known as the cross correlation. All use RBF kernels. The length scale of the E/A(n) blocks has been transformed to $k_{\rm F}^{\rm PNM}$ as discussed in the text. Hence, points of equal density between E/N(n) and E/A(n) lie on the diagonal band of the off-diagonal blocks, making them the most highly correlated, but the E/A(n) autocorrelation is unchanged. The length scales were determined by fitting to the E/N(n) and E/A(n) coefficients independently. The correlation $\rho = 0.75$ is a prediction (verified empirically) given these length scales.

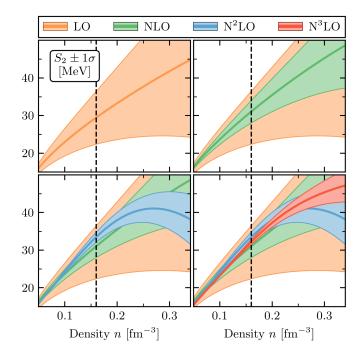

FIG. 7. The analog of Fig. 12 in the main text, but for the $\Lambda = 450 \text{ MeV}$ potentials and similar to Fig. 3, but these are the order-by-order predictions of the symmetry energy $S_2(n)$.

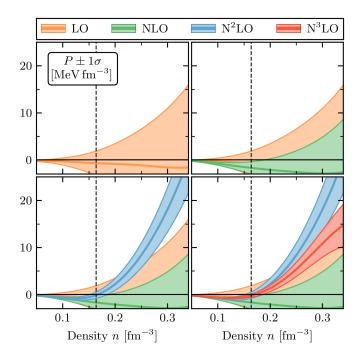

FIG. 8. The analog of Fig. 13 in the main text, but for the $\Lambda = 450 \,\text{MeV}$ potentials. Order-by-order predictions of the pressure P(n) of SNM, including differentiation and truncation uncertainty.

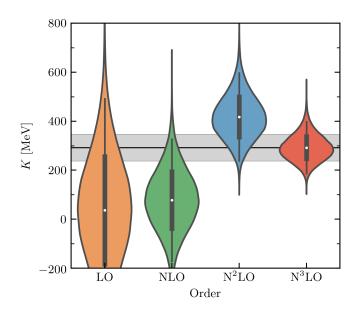

FIG. 9. The analog of Fig. 14 in the main text, but for the $\Lambda = 450 \,\text{MeV}$ potentials. Violin plots of the incompressibility K of SNM, shown order-by-order. Curves show the entire smoothed posterior (and its reflection). Each posterior includes differentiation and truncation uncertainty, and are marginalized over all plausible saturation densities $n_0 = 0.17 \pm 0.01 \,\text{fm}^{-3}$, see the main text. Dots and bars indicate the mean value, along with the 1σ and 2σ uncertainties. The black line and gray band extends the N³LO mean and 1σ uncertainty to more easily compare chiral orders.
