

- Tracemax -

A Novel Single Packet IP Traceback Strategy for Data-Flow Analysis

Peter Hillmann, Frank Tietze, and Gabi Dreo Rodosek
Universität der Bundeswehr München

Scenario

Motivation:

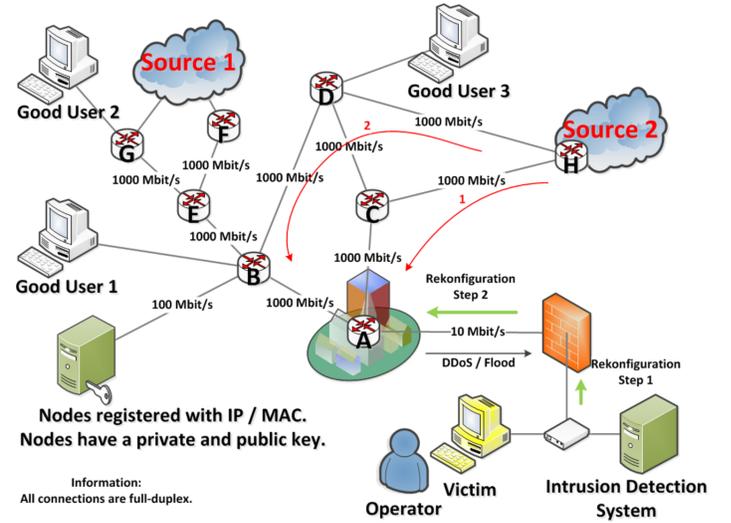

- ▶ Increasing number and quality of attacks on IT systems.
- ▶ Multiple sources and attackers (e.e. DDoS), attacks in collective.
- ▶ Necessity of an adequate defense system.
- ▶ Unique, provable identification of the attackers including traceback and localization.

Assumptions:

- ▶ Dynamically changing routes.
- ▶ Packets get lost and the order within a connection can get changed.
- ▶ Attackers can generate any packet with any faked parameters.
- ▶ Attackers can cooperate and have knowledge about traceback strategies.

Requirements:

- ▶ Single packet traceback.
- ▶ Detect and differentiate multiple attackers.
- ▶ Fast path reconstruction and preventive applicable.
- ▶ Traced router / Locations of more than 50 hops.

Application areas:

- ▶ Improved attack detection, additional information for IDS / IPS.
- ▶ Identification of *Covert Channels*.
- ▶ Verification of *Zone Routing* and *Load-Balancing*.
- ▶ Support for network analyses and routing anomalies.

Tracemax

1. Pre-configuration and ID assignment

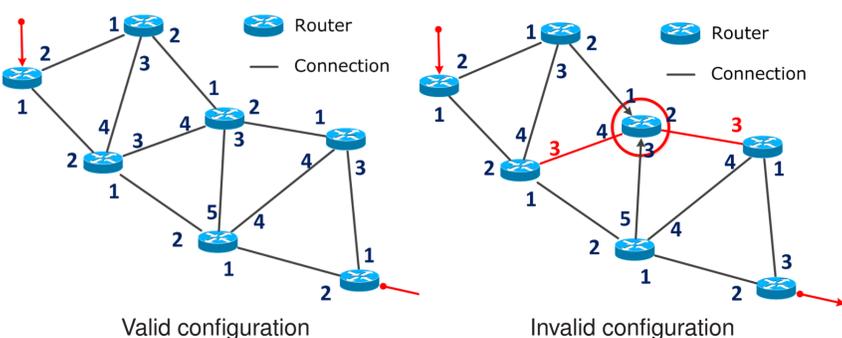

- ▶ Each physical port of every network component gets an ID assigned. (oriented on the port number; can be seen as lower ISO/OSI layer information)
- ▶ IDs are assigned in advance and not unique throughout the entire system.
- ▶ Every router is not allowed to get the same incoming ID of several connected routers. (This is achieved by incrementing one of the intended IDs. Multiple solutions are possible.)
- ▶ IDs are usually very small (≤ 6 Bits).

2. Marking scheme

- ▶ Every router on the path writes the predefined ID in the Option Field of the IP packet. (official Space with no side effects)
- ▶ Marking a packet with the ID of the outgoing interface before passing.
- ▶ Next router can prove the value.
- ▶ Option Field has sufficient size of max 40 Bytes: 6 Bits ID is much smaller than 32 Bits IP address.
- ▶ Only slight increase of network load.
- ▶ Abstract IDs do not provide private topology information of an ISP.

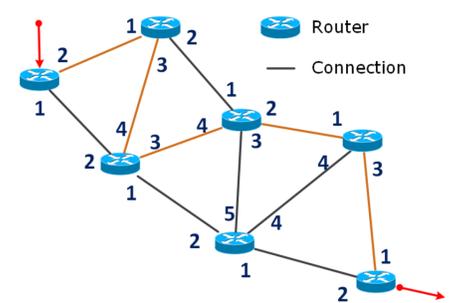

3. Reconstruction scheme

- ▶ Receiver extract the IDs out of the IP header.
- ▶ The sequence of IDs defines the used connections and thereby the path of the packet.
- ▶ Last endpoint of capturing must be known.
- ▶ Correlation of the sequence with the network infrastructure and the predefined IDs.
- ▶ Process: Step-by-step backwards, starting from the receiver node until the last marked node is found.
- ▶ Example ID sequence: 23323 \leftarrow

Version	IHL	Type of Service	Total Length	
Identification		Flags	Fragment Offset	
Time to Live		Protocol	Header Checksum	
Source IP-Address				
Destination IP-Address				
Options (+ Padding)				

IP header version 4

Path reconstruction

Implementation and Evaluation

- ▶ Prototypic implementation using the tool *Scapy*, written in Python - see paper.
- ▶ Preamble of the Option Field: '\x56\x28'
- ▶ 1 Bit Copied Flag = no
- ▶ 2 Bits Option Class = measurement parameter
- ▶ 5 Bits Option Number = unassigned option number
- ▶ 8 Bits Option Length = as required, dynamic
- ▶ Realistic experiments: real network with multiple network components and several computer.
- ▶ Traces are recorded by *Wireshark*.
- ▶ The Table compares Tracemax with the existing strategies: + advantage; - disadvantage; o neutral.

Algorithms	Traced Hops / Locations	Effectiveness	Efficiency	Robustness	Scalability	Costs	No ISP cooperation	Deploy entire Sub-Network	Short Detection Time	Preventive usable	Single Packet Traceback	Defect multiple senders
