

Physical layer:
Channel coherence time $> 1\text{ms}$

Link layer:
Queueing delay $< 1\text{ms}$

Optimal power control:
Channel inverse

Issues:
Unbounded transmit power;
Outage probability cannot characterize link-layer packet losses

Solution:
Proactive packet dropping

Performance limit:
Optimizing
 $\varepsilon_c, \varepsilon_q, \varepsilon_p$

Approach the limit:
Setting
 $\varepsilon_c = \varepsilon_q = \varepsilon_p = \varepsilon_{\text{tot}}^{\text{max}} / 3$

Optimizing the packet loss probabilities are unnecessary

Do we need to optimize delay components?

Yes. Why?

R and E_B are insensitive to packet loss probabilities,
but are sensitive to delay components
