

Repeat at different times  $t$

Take two snapshots of system at  $t_1$  and  $t_1+dt$

Extract positions and velocities by tracking particles

Convert to dimensionless variables: Divide the variables by their maxima

Repeat: Increase  $r_{\text{eff}}$  until  $f$  is smooth over  $q$  space

Repeat "infinite" times for every point of  $q$

Determine the point of interest,  $q$ , in the phase-space

Compute the distance  $d_i$  between any observed particle and  $q$

For each particle calculate  $\exp(-(d_i/r_{\text{eff}})^2)$

Unnormalized  $f(q)$  = add all the computed exponentials

Calculate  $N$ : Add unnormalized  $f$  of all  $q$

Calculate  $f(q,t)$  at time  $t$ : Divide unnormalized  $f(q)$  by  $N$

If  $f(q,t)$  at different times is equal, the system is steady
