

Step 1: Mode Decomposition

Step 2: Feature Engineering

Constructing the feature vector of event j , $\phi_j \in \mathbb{R}^d$

(i) Remove the redundant modal information present in the complex conjugate modes ($p' = p/2$)

(ii) Keep the residues of m' out of m PMUs with the largest residue magnitudes

$\phi_j \in \mathbb{R}^d \Rightarrow$ **Feature Selection (filter method)** $\Rightarrow \phi'_j \in \mathbb{R}^{d'}$
where $d' \ll d$

Step 3: Classification

Classifier

Generation Loss ✖

Line Trip ✔

- MSMPM: Multi-signal matrix pencil method
- $d = 2N_{ch}(p' + m'p')$
- m' : Number of considered PMUs
- p' : Number of distinct modes
- N_{ch} : Number of channels
