

For each  $D_{\text{train}}^{(b)}$ , rank features based on different correlation measures and remove all the features except  $d'$  with the highest correlation

$$R_{\text{F}}^{(b)} = \{f_1^F, f_2^F, \dots, f_{d'}^F\}$$

$$R_{\text{S}}^{(b)} = \{f_1^S, f_2^S, \dots, f_{d'}^S\}$$

$$R_{\text{M}}^{(b)} = \{f_1^M, f_2^M, \dots, f_{d'}^M\}$$

$$R_{\text{P}}^{(b)} = \{f_1^P, f_2^P, \dots, f_{d'}^P\}$$

$$R_{\text{K}}^{(b)} = \{f_1^K, f_2^K, \dots, f_{d'}^K\}$$

For each filter  $x$ , extract the best  $d'$  features with maximum occurrence among all the top  $d'$  features obtained from bootstrap  $\cup_{b=1}^B R_{\text{x}}^{(b)}$ .

Optimal set of  $d'$  features obtained from each filter:

$$\theta_{\text{F}}, \theta_{\text{S}}, \theta_{\text{M}}, \theta_{\text{P}}, \theta_{\text{K}}$$
