Model Predictive Control (MPC) under Disturbances and Uncertainties:  
Safety, Stability and Learning

### **Novelty of the presented results:**

Planning and control for autonomous vehicles usually are hierarchical separated. While the planner layer designs a path according to the mission goal, the controller should keep the system close to the planned course, despite changing environments, disturbances, and model plant mismatch. Classically, planning is performed on a slow time scale without considering current control limitations. Increasing performance demands and the operation in highly dynamic environments require a fast re-evaluation of the planning and tight integration of control and planning to guarantee collision avoidance and safety. We propose an integrated hierarchical predictive control and planning approach to tackle this challenge. Planner and controller are based on the repeated solution of moving horizon optimal control problems. As a main feature the planner can choose different low-level controller modes for increased flexibility and performance instead of using a single controller with a large safety margin for collision avoidance under uncertainty.

The overall contributions of this work are:

- We present a hierarchical approach for planning and control, exploiting on both layers a moving horizon MPC formulation. The layers are tightly integrated and exchange information's in form of modes selected for the controller by the planner.
- We outline a MILP planning approach operating on a moving horizon, which takes the different modes of the controller into account, by introducing binary decision variables, which activate/deactivate these modes, to overcome challenges of conservatism.
- We outline a low-level tube MPC controller, which provides safety bounds, i.e., tubes, for the different modes, e.g., velocities. This controller guarantees in combination with the planning level constraint satisfaction and collision avoidance.
- Finally, we demonstrate our approach, considering an UAV operating in a 3D environment.

### **Keywords related to the special issue:**

The results presented focus on the following topics of the special issue

- Robust MPC schemes subject to uncertainty
- Path following and path planning
- MPC with disturbance/uncertainty preview
- MPC for planning and decision making under uncertainty
- Applications from aerospace, mechatronics, robotics, automotive
