## I. BASIS SET TRUNCATION ERRORS (BSTE)

We carried out fully numerical<sup>1</sup> Hartree–Fock and density functional calculations for the  $1s$  state of various ions with the finite element method (FEM) using the HELFEM program<sup>2–4</sup>. The calculations employed 5 radial elements, affording  $nE_h$  level accuracy even for Kr<sup>35+</sup>. The basis set truncation error (BSTE) in the AHGBSP3-9 basis set, defined as the difference of the energy from the Gaussian-basis calculation with PySCF to that of the FEM calculation with HELFEM,

$$\Delta_n^{\text{method/basis}} = E_n^{\text{method/basis}} - E_n^{\text{method/FEM}} \geq 0 \quad (1)$$

was determined for the  $1s$  ground state of  $Z^{(Z-1)+}$  for  $Z \in [1, 36]$ . The BSTE was determined for unrestricted Hartree–Fock (UHF) as well as the SPW92 and PBEsol functionals; the results are shown in figure S1. The average BSTE is similar for all three methods, i.e.,  $6.1 \times 10^{-7} E_h$  for UHF,  $6.0 \times 10^{-7} E_h$  for SPW92, and  $6.9 \times 10^{-7} E_h$  for PBEsol, and the BSTE increases with increasing  $Z$ . Clearly, all the errors are below the aimed accuracy threshold of  $5 \times 10^{-5} E_h$ .

The BSTEs for the  $1s$ ,  $2p$ , and  $3d$  states are studied at the UHF level of theory in figure S2. These results clearly show that the AHGBSP3-9 basis set used in all calculations of this work has uniform accuracy for all states.

Figure S1. Basis set truncation error  $E_{\text{GTO}}^{1s} - E_{\text{FEM}}^{1s}$  in the AHGBSP3-9 basis set for the  $1s$  state in calculations performed with UHF compared to the SPW92 and PBEsol functionals. The UHF and SPW92 data are on top of each other.

Figure S2. Basis set truncation errors  $E_{\text{UHF}} - E_{\text{exact}}$  for the AHGBSP3-9 basis set for the  $1s$ ,  $2p$ , and  $3d$  states.

## II. FUNCTIONAL RANKINGS AND BAR CHARTS

A ranking of the functionals from best (lowest mean state error, MSE) to worst (largest MSE) for  $1s$  states is given in table S1, for  $2p$  states in table S2, and for  $3d$  states in table S3. The ranking for the overall error (OE) is shown in table S4. The best performing functionals for the  $1s$ ,  $2s$ , and  $3d$  states as well as overall are summarized in table S5. To facilitate the visual interpretation of the MSEs, bar charts for the  $1s$ ,  $2s$ , and  $3d$  states are provided in figure S3: see figure 3(a) for  $1s$ , figure 3(b) for  $2p$  and figure 3(c) for  $3d$ . A bar chart of the OE is given in figure S4.

## III. COMPARISON TO LITERATURE DATA FOR $1s$ STATES

A comparison to the results of Lonsdale and Goerigk<sup>5</sup> for the  $1s$  state is shown table S6. As the study of Lonsdale and Goerigk<sup>5</sup> did not include K and Ca (see notes in Figs. 3 and 10 in Ref. 5), we exclude them for this comparison. Even though Lonsdale and Goerigk<sup>5</sup> used a different basis set and quadrature grid, our values are in reasonable agreement, with relative differences of only some percent for most functionals. The sole exception is the M11-L functional, for which the functional error reported in Lonsdale and Goerigk<sup>5</sup> is 13% smaller than what we find in this study.

Further study into this issue shows that the difference for M11-L is caused by the basis set: the unc-aug-cc-pVQZ basis was used in Ref. 5 while this work uses the AHGBSP3-9 basis set. The basis set dependence is studied in table S7 for HF and the PBE, TPSS, revTPSS, M06-L, M11-L, and B97M-V functionals using various

Figure S3. MSE for the  $1s$ ,  $2p$ , and  $3d$  states for 56 functionals.

augmented correlation consistent basis sets<sup>6,7</sup> in their uncontracted form (unc-aug-cc-pVXZ), augmented polarization consistent basis sets<sup>8,9</sup> in uncontracted form (unc-aug-cc-pC-n) and the hydrogenic Gaussian basis set

series<sup>10</sup> used in this work in both augmented and non-augmented form. For comparison, values computed with FEM<sup>1-4</sup> are also included for most functionals. FEM data is not available for M11-L as the calculations failed

Figure S4. OE for 56 functionals.

to converge with this functional, nor for B97M-V which includes non-local correlation that is not available at the moment in HELFEM.

In all cases, the hydrogenic basis sets yield the lowest energies out of the Gaussian basis sets. Furthermore, the AHGBSP3-9 values are very close to FEM values except for M06-L, confirming the usefulness of the hydrogenic Gaussian basis sets for benchmark calculations.

The values from unc-aug-cc-pVQZ used by Lonsdale and Goerigk<sup>5</sup> and the AHGBSP3-9 basis used in this work differ by  $51.7\mu E_h$  for HF,  $56.0\mu E_h$  for PBE,  $83.0\mu E_h$  for TPSS, and  $70.8\mu E_h$  for revTPSS, with the values of this work being more converged to the basis set limit. The remaining three functionals are more basis set dependent: the values differ by  $0.64mE_h$  for M06-L,  $4.78mE_h$  for M11-L and  $0.22mE_h$  for B97M-V. Because the density functionals already yield total energies that are too negative, the improvement in the accuracy of the basis set directly affect the error metric for the functionals.

M06-L and M11-L appear to be pathologically grid dependent, which is further supported by the FEM calculations: we were unable to converge M11-L with FEM, while M06-L shows an unexpectedly large difference of  $0.29mE_h$  between the AHGBSP3-9 value and the FEM value.

Table S6. Comparison of results for the  $1s$  state of the present work (PW) with the corresponding values of Lonsdale and Goerigk (LG) from Ref. 5. Note that we used our MSE definition for PW and LG, which is unitless. In addition, the absolute percentage error  $\text{APE} = |((\text{LG} - \text{PW})/\text{PW})| \times 100\%$  is reported.

Name	PW	LG	APE [%]
