

## Supplementary Material

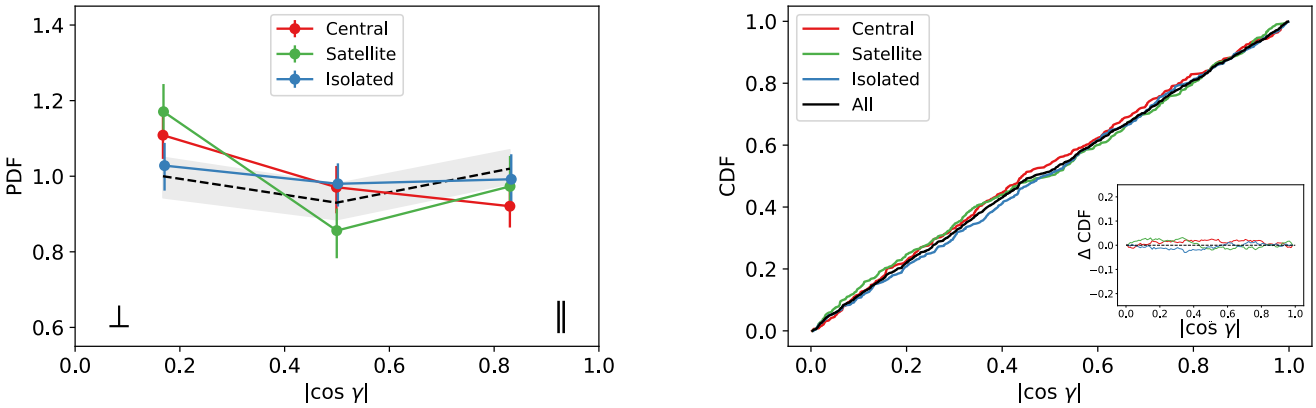

**Figure S1:** PDFs (left) and CDFs (right) of the spin–filament alignments for 1071 SAMI galaxies in ranges of  $(V/\sigma)_e$  (top) and  $\lambda_e$  (bottom). A statistically significant preference for perpendicular alignments is found for lower  $(V/\sigma)_e$  and  $\lambda_e$  values. Overall, similar PDFs are found as a function of  $(V/\sigma)_e$  and  $\lambda_e$ .

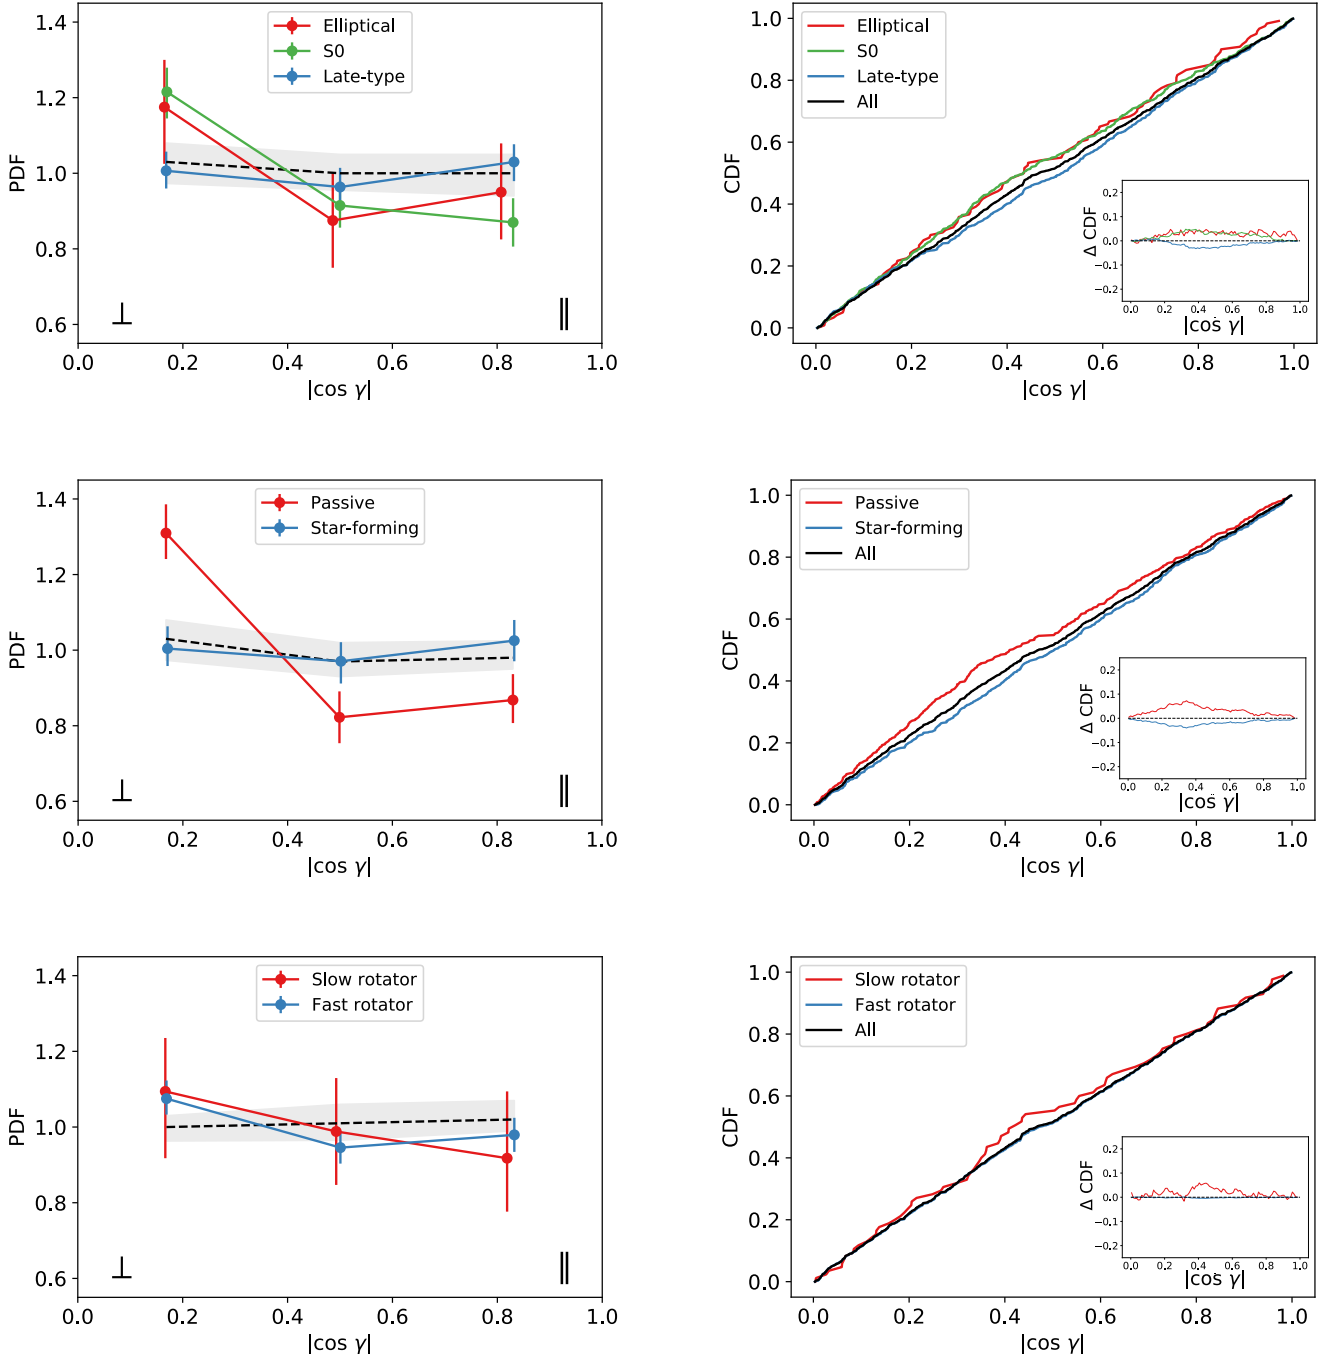

**Figure S2:** PDFs (left) and CDFs (right) of the spin–filament alignments for 1121 SAMI galaxies in ranges of age. A statistically significant preference for perpendicular alignments is found for older galaxies. A significant difference is found between the  $|\cos \gamma|$  distributions of the youngest and oldest galaxies.

**Figure S3:** The distribution of  $\lambda_e$  and ellipticity for 1071 SAMI galaxies, colour-coded according to  $M_{\text{bulge}}$ . Galaxies with  $\lambda_e < 0.5$  mostly have high  $M_{\text{bulge}}$  values, consistent with their significant tendency to perpendicular spin–filament alignments, while galaxies with  $\lambda_e > 0.5$  show a broader range in  $M_{\text{bulge}}$ , consistent with their uniform distribution in  $|\cos \gamma|$ .

**Figure S4:** PDFs (left) and CDFs (right) of the spin–filament alignments for 1121 SAMI galaxies divided into group centrals, satellites and isolated galaxies. A statistically significant preference for perpendicular alignments is found for group central galaxies.

**Figure S5:** PDFs (left) and CDFs (right) of the spin-filament alignments for the SAMI galaxies divided according to visual morphology (top), spectral classification (middle) and kinematic morphology (bottom). A statistically significant perpendicular alignment is found for S0 galaxies and passive galaxies; hints of a similar tendency are seen for the smaller sample of ellipticals and slow rotators. Late-type galaxies, star-forming galaxies, and fast rotators are consistent with uniform PDFs. A significant difference is detected between the  $|\cos \gamma|$  distributions of ellipticals+S0s and late-types, and also between passive and star-forming galaxies.
