

## Generation of 3D hyperspectral models (point clouds)

❶ Generating hyperspectral point clouds directly from hyperspectral 2D frame images (structure from spectra?)

- Finding common features
- Disadvantages: poor radiometric and spectral resolutions

❷ Combine hyperspectral images with point clouds (from RGB, collected by LiDAR)

① Base on image

• Feature-based

- Rely on the common features in the template image and the reference image to solve the transformation parameters

• Intensity-based

- Using similarity measures to estimate the degree of correlation between images
- Employ LiDAR data to generate intensity maps

② Base on system calibration

- Based on system calibration aim to align the data obtained by different sensors in the same geographic coordinate system

③ Does not rely on the intensity information and GCPs

- GCPs (ground control points)
- More reliable and wider applicability
