

Generate python code to answer the question.

Q: Marie ordered one chicken meal that costs \$12, 5 packs of milk that costs \$3 each, 4 apples that cost \$1.50 each, and some boxes of pizza. Marie paid a total of \$50. How many boxes of pizza did Marie order if each box costs \$8.50?

Language
Model

```
chicken_meal = 12
milk_packs = 3 * 5
apple = 1.5 * 4
total = chicken_meal + milk_packs + apple + 8.5 * x
# where x is the number of boxes of pizza
# we need to find the value of x
# total cost is $50
# so, we can write the equation as:
50 = chicken_meal + milk_packs + apple + 8.5 * x
# solving for x
x = (50 - chicken_meal - milk_packs - apple) / 8.5
print("Marie ordered", x, "boxes of pizza.")
```

Python
Interpreter

Bug report:

```
50 = chicken_meal + milk_packs + apple + 8.5 * x
^
SyntaxError: cannot assign to literal
```

Language
Model

```
chicken_meal = 12
milk_packs = 3 * 5
apple = 1.5 * 4
# initialize x to 0
x = 0
total = chicken_meal + milk_packs + apple + 8.5 * x
# where x is the number of boxes of pizza
# we need to find the value of x
# total cost is $50
# so, we can write the equation as:
# 50 = chicken_meal + milk_packs + apple + 8.5 * x
# solving for x
x = (50 - chicken_meal - milk_packs - apple) / 8.5
print("Marie ordered", int(x), "boxes of pizza.")
```

output: 2 ✓
