

generate a loss class such that vehicle 1 should collide with vehicle 2.

User Query

```
# The function transforms positions from agent coordinates into world coordinate.
def transform_coord_to_world(pos_agent):
    ...
    return pos_world
```

Helper Functions

**Example1\_query:** generate a loss class such that vehicle 1 should always drive with acceleration below acc\_limit.

**Example1\_response:**

```
Class AccLimitLoss:
def forward(self, x):
    # Select the relevant agent
    x_i = select_agent_ind(x, 1)
    # Select the acceleration
    acc = x_i[..., 4]
    # Estimate the acceleration deviation
    acc_dev = torch.abs(acc) - self.acc_limit
    # Clip the negative values to 0
    loss = torch.clip(acc_dev, min=0)
    return loss
```

Paired Examples

**GPT4**

**Response:**

```
class Collision_Loss:
def forward(self, x):
    pos_pred = x[..., :2]
    pos_pred_world = transform_coord_to_world(pos_pred, data_batch)
    pos_pred_i_world = select_agent_ind(pos_pred_world, 1)
    pos_pred_j_world = select_agent_ind(pos_pred_world, 2)
    # Compute the distance between the two vehicles
    dist = torch.norm(pos_pred_i_world - pos_pred_j_world, dim=-1)
    # Compute the collision loss by penalizing the distance greater than the collision radius
    loss = torch.clip(dist - self.collision_radius, min=0)
    return loss
```

Differentiable Loss Function in Python
