

Low-Rank Mixing Model

$$Y = E \times A + N$$

Diagram illustrating the Low-Rank Mixing Model. The observed data Y (a 3D volume) is equal to the product of the endmember matrix E (containing spectral signatures for Water, Tree, and Soil) and the abundance matrix A (a 3D volume), plus the noise N (a 3D volume).

Supervised Unmixing

$$Y = E \times ? + N$$

Diagram illustrating Supervised Unmixing. The observed data Y is equal to the product of the known endmember matrix E and an unknown abundance matrix (represented by a red question mark), plus the noise N .

Unsupervised (Blind) Unmixing

$$Y = ? \times ? + N$$

Diagram illustrating Unsupervised (Blind) Unmixing. The observed data Y is equal to the product of two unknown matrices (both represented by red question marks), plus the noise N .

Sparse and Redundant Model

$$Y = D \times X + N$$

Diagram illustrating the Sparse and Redundant Model. The observed data Y is equal to the product of the dictionary matrix D (containing spectral signatures for Water, Tree, and Soil) and the sparse coefficient matrix X (a 3D volume), plus the noise N .

Semisupervised Unmixing

$$Y = D \times ? + N$$

Diagram illustrating Semisupervised Unmixing. The observed data Y is equal to the product of the known dictionary matrix D and an unknown sparse coefficient matrix (represented by a red question mark), plus the noise N .
