

Supplementary Material

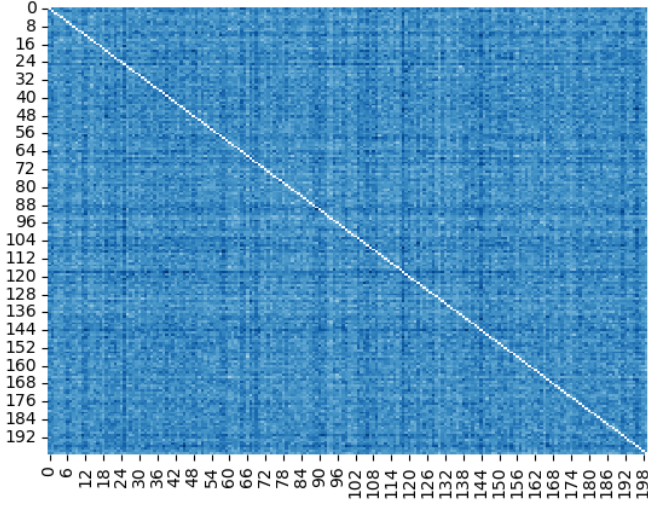

Fig. 1. Cosine distance among local clients in the drugs review dataset

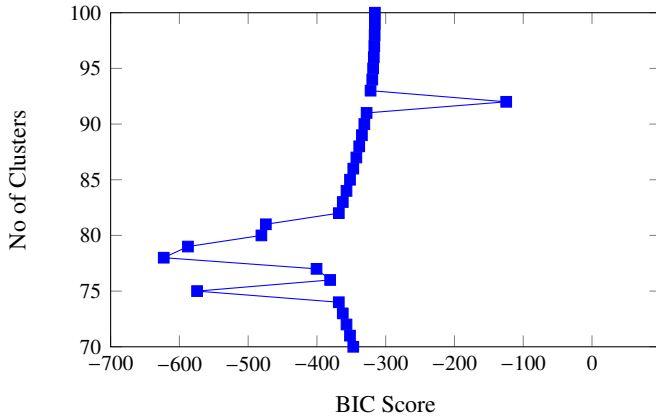

Fig. 2. BIC score to determine the number of clusters in drugs review dataset

In this section, results related to the drugs review dataset are presented. The cosine distance among all 200 local models, trained at clients, is calculated to examine their similarity in terms of the models' output layer weights, as shown in Fig. 1. The matrix heatmap ranges on a scale from 0 to 0.5, where 0 indicates no cosine distance between the client output layer values, and 0.5 represents the maximum cosine distance.

The determination of the number of clusters among the 2191 local clients is shown in Fig.2, where the lowest BIC score corresponds to 78 clusters in the global server model. After identifying the clusters, the distribution-based clustering method, specifically the Gaussian Mixture Model (GMM)[1], was applied.
