

Active galactic nucleus (AGN) jets can suppress cooling flows (and therefore quench star formation) in massive galaxies if the following three criteria are met.

1. Moderate jet energy flux

Enough energy for cocoon expansion to balance gas cooling, but not so much energy as to exceed escape velocity at R_{cool} .

$$\rho_R R^2 v_{\text{exp}}^3 \gtrsim \dot{E}_{\text{tot}, J} \gtrsim \dot{M}_{\text{cool}} v_{\text{ff}} [R_{\text{cool}}]^2$$

2. Long cooling time within jet cocoon

Longer than time to reach R_{cool} .

$$t_{\text{cool}}[R_{\text{cool}}] > t_{\text{expansion}}[R_{\text{cool}}]$$

Can be achieved by thermal or kinetic jets with high specific energy or CR jets.

3. Wide jet cocoon

Width of cocoon at R_{cool} is enough to suppress the cooling flow over a wide solid angle.

$$\left. \frac{R_{\text{cocoon}}}{z_{\text{cocoon}}} \right|_{R_{\text{cool}}} \gtrsim 1$$

Can be achieved by jets with a high non-kinetic component, very light kinetic jets, or jets with initially wide angles.
