

## Description of supporting movies

### Movie S1: Periodic detachment of liquid lenses

Liquid: Dodecane

Flow rate:  $Q = 100 \mu\text{L}/\text{min}$

Injection of liquid 2 is done through a needle (its tip is visible at the top) resting against a vertical plate. The upper horizontal line is the triple contact line of the meniscus of liquid 1 (water) on the plate. The lower horizontal line is the image of the submerged bottom of the plate.

### Movie S2: Example of periodic pinch-off (I) in the quasi-static limit i)

Liquid: Dodecane

Flow rate:  $Q = 5 \mu\text{L}/\text{min}$

Corresponding to  $\text{Ca Bo}_2 = 2.2 \times 10^{-5}$

For quasi-static dripping (i), pinch-off occurs close below the contact line of the water meniscus on the vertical plate.

### Movie S3: Example of periodic pinch-off (I) in the viscous limit ii)

Liquid: Mineral Oil S200

Flow rate:  $Q = 50 \mu\text{L}/\text{min}$

Corresponding to  $\text{Ca Bo}_2 = 1.4 \times 10^{-2}$

For viscous pinch-off (ii), the floating liquid ligament stretches along the water meniscus into a thin thread, which eventually pinches-off.

### Movie S4: Transition from periodic pinch-off (I) to no pinch-off (II)

Liquid: Mineral Oil RTM30

Flow rate:  $Q = 20 \mu\text{L}/\text{min}$

Corresponding to  $\text{Ca Bo}_2 = 7.7 \times 10^{-2}$

Liquid lenses detach, but the ligament width fluctuates before pinching-off. Pinch-off occurs when most of the lens volume rests on the horizontal part of the bath. The horizontal line is the image of the submerged bottom of the plate; the triple contact line (out of the video frame) is located slightly above.

### Movie S5: No pinch-off regime (II) (continuous feeding)

Liquid: Mineral Oil RTM30

Flow rate:  $Q = 50 \mu\text{L}/\text{min}$

Corresponding to  $\text{Ca Bo}_2 = 0.19$

No pinch-off occurs, and a liquid ligament continuously feeds a floating liquid puddle. The horizontal line is the image of the submerged bottom of the plate; the triple contact line (out of the video frame) is located slightly above.
