

Prompt:

You are an expert Python programmer, and here is your task:

In the Python language, start by creating a **PME** class. Within the **PME** class, define a public function called **prime_number**. Within this function, validate whether a given integer **number** is a prime number. If it is prime, the function should return **True**; otherwise, it should return **False**.

Your code should pass these tests:

```
"PME().prime_number(17) == True"
```

```
[BEGIN]
```

```
class PME:
    def prime_number(self, number):
        if number < 2:
            return False
        for i in range(2, int(number**0.5) + 1):
            if number % i == 0:
                return False
        return True
```

```
[DONE]
```

⋮

Firstly, design an **ES** class using Python language, which has instance attributes **nums** and **k**, a private function **private_Equal_sum**, and a public function **public_Equal_sum**. Then, in the private function **private_Equal_sum**, determine whether it is possible to divide this array into **k** non-empty subsets with equal sums, based on a given integer array **nums** and a positive integer **k**. Finally, call the private function **private_Equal_sum** in the public function **public_Equal_sum** to return the result.
