You

Firstly, design an `MT` class using the Python language, which has instance attributes `words` and `k`, a private function `private_Most_times`, and a public function `public_Most_times`. Then, in the private function `private_Most_times`, return the top `k` most frequently occurring words from a given word list `words` and an integer `k`. Finally, call the private function `private_Most_times` in the public function `public_Most_times` to return the result.

`private_Most_times` ❌

ChatGPT

Certainly! Here's an example implementation of the `MT` class in Python with the specified requirements:

```
python Copy code

from collections import Counter

class MT:
    def __init__(self, words, k):
        self.words = words
        self.k = k

    def public_Most_times(self):
        return self.private_Most_times()

    def private_Most_times(self):
        # Count the occurrences of each word
        word_counts = Counter(self.words)

        # Get the top k most common words
        most_common_words = word_counts.most_common(self.k)

        return most_common_words

# Example Usage:
word_list = ["apple", "banana", "apple", "orange", "banana", "apple", ""]
k_value = 2

mt_instance = MT(words=word_list, k=k_value)
result = mt_instance.public_Most_times()

print(f"Top {k_value} most common words: {result}")
```
