The computer controlled video display system includes a Z-buffer for storing Z values and a frame buffer for storing pixel values. The Z-buffer has a single, bi-directional data port which is coupled to a graphics update controller which is substantially similar to the prior art graphics update controller. The frame buffer may be a single port random access memory or a dual port random access memory. <a href="#"># The method of the invention for updating the Z-buffer with new Z values to replace the old Z values begins with the calculation of a new Z value and a new pixel value for each pixel location in a plural</a></a></p>	<b>Writing Style = 0.13</b> <p>... ual sources observed. <a href="#"># The observations were arranged in duty cycles. Each duty cycle covered a subset of two to four close-by sources (with integration times between 30 and 60 s in each source position), in a similar way as the duty cycles described in Paper III. The duty cycles were designed to maximize the antenna elevations, which optimize the quality of the differential phase delays. We show in Fig. 1 the time distribution of all the observations. The frequency-switching changes were applied in two types of duty cycles, which were alternated every four iterations. In the first type of cycle (optimized for the frequency-switching calibration, see Sect. 3.2), half of the switchings were applied while the antennas were slewing among sources. If AL and AH are observations of source A at 14.4 GHz and 43.1 GHz, respectively, the duty cycles were arranged as This approach saves some time due to switching. In the second type of duty cycle, observations of different sources at the highest frequencies were put close in time: This approach</a></p>	<b>Writing Style = 1.01</b> <p>... <a href="#"># To travel a certain distance you must first traverse half of it. <a href="#"># Makes perfect sense. Two is one plus one. And one is one-half plus one-half. But don't be fooled by this seemingly innocent reasoning; it's a trap!</a> (Admiral Ackbar!) <a href="#"># To appreciate what's going on-and connect Zeno's paradox back to calculus-let's pretend Zeno is in line at Starbucks, two feet away from the cash register. He's almost done scanning the menu when the barista yells out "next!" And that's when poor Zeno panics. He must now walk two feet, but because of his minds</a> et, he walks only half that distance with his first step. He then walks half of the remaining distance with his second step. (Can you imagine how annoying those in line behind him are getting?) The figure below keeps track of the total distance Zeno has walked and the change in distance <b>Ad</b> after each of his steps. <a href="#"># Fig. 1.2: Zeno trying to walk a distance of 2 feet by traversing half the remaining distance with each step. (Reprinted, with permission, from Calculus Simplified.) <a href="#"># Here's a tabu</a></a></a></p>

The property that <math>\setminus(M^2=J\setminus)</math>, along with special properties of <math>\setminus(J\setminus)</math>, allows you to conclude that higher powers of <math>\setminus(M\setminus)</math> are all just multiples of <math>\setminus(J\setminus)</math>; in particular, examining <math>\setminus(M^3=MJ=JM\setminus)</math> reveals that every node in the graph has as the same number of neighbors <math>\setminus(k\setminus)</math>. So <math>\setminus(M^3=kJ\setminus)</math>. (And <math>\setminus(k^2=n\setminus)</math> because <math>\setminus(k^2\setminus)</math> is the number of two-step paths, which lead uniquely to each node in the graph.) Notice that because of this neighbor property, <math>\setminus(M\setminus)</math> sends a column vector of all 1 ones to a column vector of all k's, so <math>\setminus(M\setminus)</math> has an eigenvalue <math>\setminus(k\setminus)</math>. Based on the powers of <math>\setminus(M\setminus)</math>, <math>\setminus(M\setminus)</math> furthermore has <math>\setminus((n-1)\setminus)</math> generalized eigenvectors with eigenvalue zero. There are always exactly <math>\setminus(n\setminus)</math> independent generalized eigenvalues, and we've just found all of them. Their sum is <math>\setminus((0+0+\cdots+1)\setminus=k\setminus)</math>, which establishes the result. <a href="#"># The same procedure establishes a more general result: If there's a unique <math>r</math>-step path between every pair of nodes in a graph, then every node has <math>\setminus(k\setminus)</math></a></p>
