

Input Verilog Code	Output From General Large Language Model
<pre>module decade_counter (input clk, input reset, output reg [3:0] q); always @(posedge clk) if (reset) q <= 0; else q <= q < 9 ? q + 1 : 0; endmodule</pre>	<p>Simple: This module counts from 0 to 9 over and over on each clock pulse. It can be reset to 0.</p> <p>Intermediate: This is a decade counter module that increments a 4-bit output value q from 0 to 9 repeatedly. On each clock pulse, q is incremented by 1 as long as it's less than 9. If q is 9, it resets to 0 on the next clock edge. The synchronous reset sets q to 0 on the next clock pulse.</p> <p>Complex: This Verilog module describes a synchronous decade counter with reset capabilities. The 4-bit output bus q holds the current count state from 0 to 9. On every rising clock edge, the state increments by 1, unless the maximum count of 9 has been reached, in which case the state wraps around to 0 again.</p>
