

Mutation testing is a technique that involves modifying a program in small ways, in order to find weaknesses in a project's test suite. The goal is to change the behavior of the program, and then check whether the tests notice. When they do not, that indicates that the tests may not be as effective as the developer might have hoped.

1

Your task is to apply mutation testing to the following code:

```
...  
{{{code}}}  
...
```

2

by replacing the PLACEHOLDER with a buggy piece of code that behaves different from the original code fragment, which was:

```
...  
{{{orig}}}  
...
```

Please consider changes such as using different operators, changing constants, referring to different variables, object properties, functions, or methods.

Provide three answers as fenced code blocks containing a single line of code, using the following template:

Option 1: The PLACEHOLDER can be replaced with:

```
...  
<code fragment>  
...
```

This would result in different behavior because <brief explanation>.

Option 2: The PLACEHOLDER can be replaced with:

```
...  
<code fragment>  
...
```

This would result in different behavior because <brief explanation>.

Option 3: The PLACEHOLDER can be replaced with:

```
...  
<code fragment>  
...
```

This would result in different behavior because <brief explanation>.
