

Train

A ball travels on a path in which the height (in feet) is given by the expression $-16t^2 + 64t + 31$, where t is the time after launch. What is the maximum height of the ball?

We need to maximize the expression by completing the square to get $-16(t - 2)^2 + 95$. Since $-16(t - 2)^2$ is always non-positive, the max value is 95 feet.

We need to maximize the expression by completing the square to get $-16(t - 2)^2 + 95$. Since $-16(t - 2)^2$ is always non-positive, the max value is 95 feet. **(Original Solution)**

The expression actually represents a quadratic function of time: $h(t) = at^2 + bt + c$ When $a < 0$, the vertex of the parabola marks the max point To reveal the vertex, we complete the square as $y = a(x + \frac{b}{2a})^2 + (c - \frac{b^2}{4a})$, so the vertex is $(-\frac{b}{2a}, c - \frac{b^2}{4a})$ Another way is to calculate the derivative: $h'(t) = -32t + 64$ Setting $h'(t) = 0$ results in $t = 2$ and the maximum is $h(2) = -16 \times 2^2 + 64 \times 2 + 31 = 95$ Additionally, the second derivative, $h''(t) = -32$ feet/s² represents the acceleration of the ball and the time that it hits the ground, or when $h(t) = 0$, is $\frac{-b - \sqrt{b^2 - 4ac}}{2a} = 2 + \frac{\sqrt{95}}{4}$ seconds. **(Reflection)**

Test

An object is launched from the origin at $t = 0$, and its displacement $s(t)$ follows the following function: $s(t) = -2t^3 + 6t^2 + 3t$. Determine the time t at which the object has the highest velocity before returning to origin.

To find the maximum of the expression, we complete the square as $-2(t - \frac{3}{2})^2 + \frac{15}{2}$. Therefore, the maximum is reached when $t = \frac{3}{2}$

The velocity of the object is $v(t) = s'(t) = -6t^2 + 12t + 3$. Since $a = -6 < 0$, the maximum is reached at the vertex of the parabola, where $t = -\frac{b}{2a} = 1$
