

## Dataset Limitations

Like all language models, dolly-v2-7b reflects the content and limitations of its training data.

**Key point:** The training data contains objectionable contents, causing the model to sometimes generate them (general comment)

**Code:** General comments about inappropriate content in training data

- **The Pile:** GPT-J's pre-training corpus contains content mostly collected from the public internet, and like most web-scale datasets, it contains content many users would find objectionable. As such, the model is likely to reflect these shortcomings, potentially overtly in the case it is explicitly asked to produce objectionable content, and sometimes subtly, as in the case of biased or harmful implicit associations.
- **databricks-dolly-15k:** The training data on which dolly-v2-7b is instruction tuned represents natural language instructions generated by Databricks employees during a period spanning March and April 2023 and includes passages from Wikipedia as references passages for instruction categories like closed QA and summarization. To our knowledge it does not contain obscenity, intellectual property or personally identifying information about non-public figures, but it may contain typos and factual errors. The dataset may also reflect biases found in Wikipedia. Finally, the dataset likely reflects the interests and semantic choices of Databricks employees, a demographic which is not representative of the global population at large.

Databricks is committed to ongoing research and development efforts to improve the model's performance and safety for all individuals and organizations.

**Key point:** The training data reflects the interests/ perceptions of annotators, which may not be representative of global population.

**Code:** Possibility of biased annotations
